SHIELD INSURANCE

Dashboard Documentation

A comprehensive business guide to the Power BI report

Prepared for Mathew

Reporting period: 1 November 2022 – 30 April 2023

Dashboard landing page – navigation to the three analytical sections

How to use this document

This guide is written for a business reader who wants to understand what the Shield Insurance dashboard shows, how to navigate it, what each metric means, and what conclusions can reasonably be drawn from the available data. It is not necessary to know Power BI or DAX to use the report.

- Start with the Executive Summary for the overall picture.
- Use the Page Guides when reviewing each report page alongside the screenshots.
- Refer to KPI Definitions for the exact meaning and calculation logic behind the headline numbers.
- Read Data Limitations before using the figures in a formal business decision or presentation.

Important reading principle A dashboard shows patterns in the supplied data. It describes what is present in this six-month dataset; it does not, by itself, explain why a pattern occurred or prove future performance.

1. Executive summary

The Shield Insurance dashboard is an interactive business intelligence report designed to provide a consolidated view of customer acquisition, premium revenue, sales-channel contribution, monthly movement, customer age segments and age-related policy patterns.

Headline measure	Reported value	What it tells the reader
Total customers	26,841	Distinct customers represented in the premium transaction data.
Total premium revenue	₹989.25 million (approximately ₹98.93 crore)	Sum of final premium amounts in the dataset.
Daily customer growth rate	51.11%	Increase in distinct customers between the latest available date and the previous available date.
Daily revenue growth rate	64.39%	Increase in premium revenue between the latest available date and the previous available date.
Policy sales growth (MoM)	−41.41%	April row-count volume compared with March row-count volume, based on the measure used in the report.

At a high level, Offline-Agent is the largest sales mode by both customer count and revenue. The 36–45 age band has the largest customer count and revenue contribution in the displayed age analysis, while the Above 55 segment has the highest average revenue per customer. The monthly policy-sales measure falls from March to April 2023.

Business interpretation The report is strongest as a descriptive view of customer and premium performance. It helps identify where volume and revenue are concentrated, how the channels compare, and which age groups contribute most. It should not be treated as a causal analysis or a forecast.

2. Report at a glance

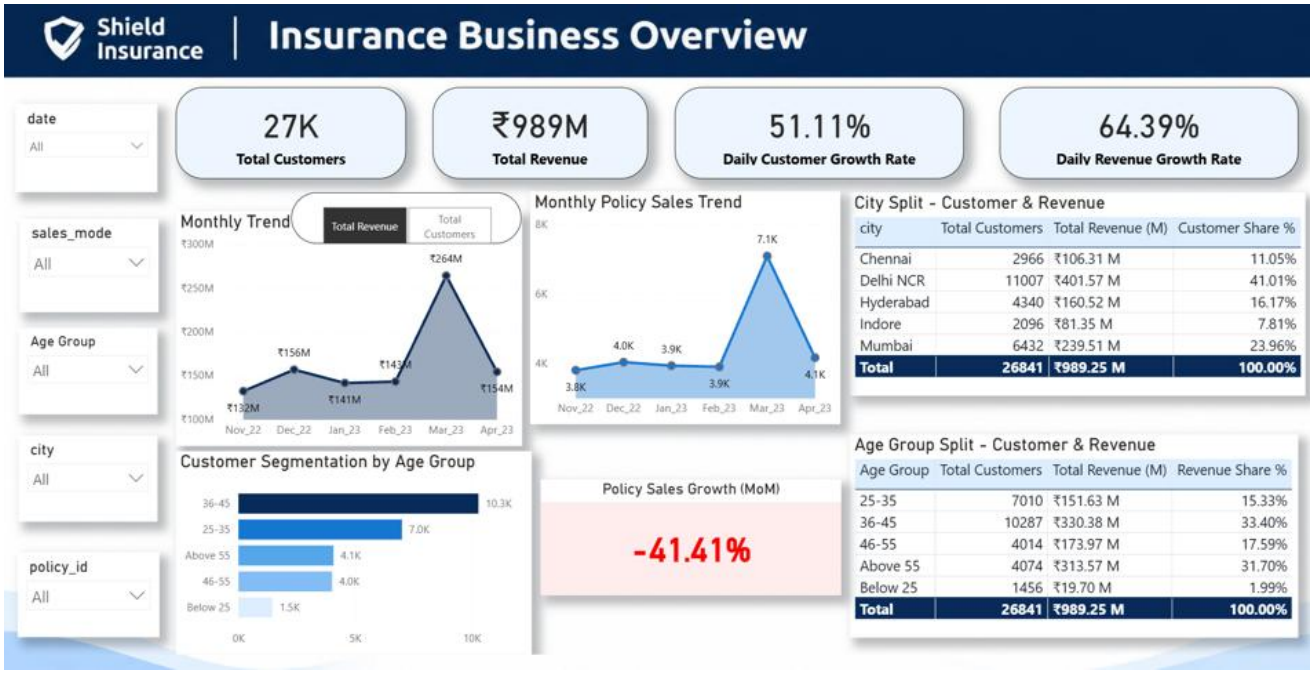

Report page	Main business question	What the page contains
Home	Where should I go to explore the business?	Navigation to Business Overview, Sales Mode Analysis and Age Group Analysis.
Business Overview	What is the overall performance and how is it changing?	Headline KPIs, monthly trends, city split, age-group split and slicers.
Sales Mode Analysis	Which channels contribute customers and revenue?	Customer and revenue tables, contribution donuts and monthly channel trends.
Age Group Analysis	How do customer and policy patterns differ by age?	Policy preference matrix, age distribution, settlement percentage, channel preference, monthly age trends and revenue table.

3. How to navigate and interact with the report

1. Open the Home page. Select one of the three dashboard sections to review.
2. Use the slicers on the left side of an analytical page to narrow the displayed data. The visible slicers include date, sales mode, age group, city and policy ID.
3. Select a value in a slicer to filter the page. Use the slicer's clear/reset option or choose All to return to the broader view.
4. Hover over chart points, bars, donut segments or table values to view Power BI tooltips when available.
5. Read charts together with their labels and tables. A chart is useful for spotting a pattern; the accompanying table provides more precise values.

Filter behaviour A slicer selection changes the visuals that are connected to it. The report is designed for interactive exploration; if a particular metric is intended to ignore a filter (for example, a latest-date KPI), its behaviour may differ from the other visuals. See the KPI notes below.

4. Page 1 – Business Overview

Business Overview page

4.1 Purpose of this page

This is the main performance-monitoring page. It brings together the size of the customer base, premium revenue, short-term daily movement, monthly policy volume, geographic contribution and age-group contribution. It is the best starting point for a manager who wants to understand the overall business before drilling into a particular channel or customer segment.

4.2 Headline KPI cards

Visual	Definition and interpretation
Total Customers – 27K	Distinct count of customer_code in fact_premiums. The exact total is 26,841. It represents unique customer IDs appearing in the premium fact table, not the number of policies.
Total Revenue – ₹989M	Sum of final_premium_amt(INR). Exact total is ₹989,252,849 (approximately ₹989.25M). This is premium revenue recorded in the supplied fact table.

Daily Customer Growth Rate – 51.11%	Compares distinct customers on the latest available transaction date (30 April 2023) with the previous available transaction date (29 April 2023). Customers increased from 225 to 340: (340−225) ÷ 225 = 51.11%.
Daily Revenue Growth Rate – 64.39%	Compares revenue on 30 April 2023 with revenue on 29 April 2023. Revenue increased from ₹8,038,245 to ₹13,214,310: (13,214,310−8,038,245) ÷ 8,038,245 = 64.39%.

4.3 Monthly Trend – Total Revenue / Total Customers

This visual provides a month-by-month view across November 2022 to April 2023. The toggle allows the reader to switch between revenue and customer count. Use it to understand the direction of the business over time, identify peaks or dips, and compare the timing of customer movement with premium revenue movement.

- Revenue answers: how much premium value was recorded in each month?
- Customers answers: how many distinct customers were recorded in each month?
- A rise in customer count does not automatically mean revenue rises by the same percentage. The average premium per customer and the mix of policies can also affect revenue.

4.4 Monthly Policy Sales Trend and Policy Sales Growth (MoM)

The monthly policy sales trend shows the monthly volume represented by rows in fact_premiums. The report's measure is COUNTROWS(fact_premiums). The April-versus-March comparison is 4,149 versus 7,081, producing a decline of 41.41%.

Metric wording The current calculation counts rows in the premium fact table. It is a policy-sales count only if each row represents one policy sale. If the source contains multiple rows per policy or repeated transactions, the business label should be interpreted as transaction-row volume rather than unique policies.

4.5 City Split – Customer and Revenue

This table compares the five cities represented in the report. Customer Share % indicates each city's proportion of the total customer count; Total Revenue (M) indicates the premium revenue associated with that city.

City	Customers	Revenue	Customer share
Chennai	2,966	₹106.31M	11.05%
Delhi NCR	11,007	₹401.57M	41.01%
Hyderabad	4,340	₹160.52M	16.17%
Indore	2,096	₹81.35M	7.81%
Mumbai	6,432	₹239.51M	23.96%
Total	26,841	₹989.25M	100.00%

Delhi NCR is the largest city segment in this dataset, contributing 41.01% of customers and approximately ₹401.57M in revenue. Mumbai is the second-largest by customer count and revenue. These figures describe the distribution in the supplied data; they do not establish market share in the cities' overall insurance markets.

4.6 Customer Segmentation by Age Group

The horizontal bar chart compares the number of customers in each age band. It makes the relative size of each segment easy to see. In the displayed report, 36–45 is the largest group, followed by 25–35 and Above 55.

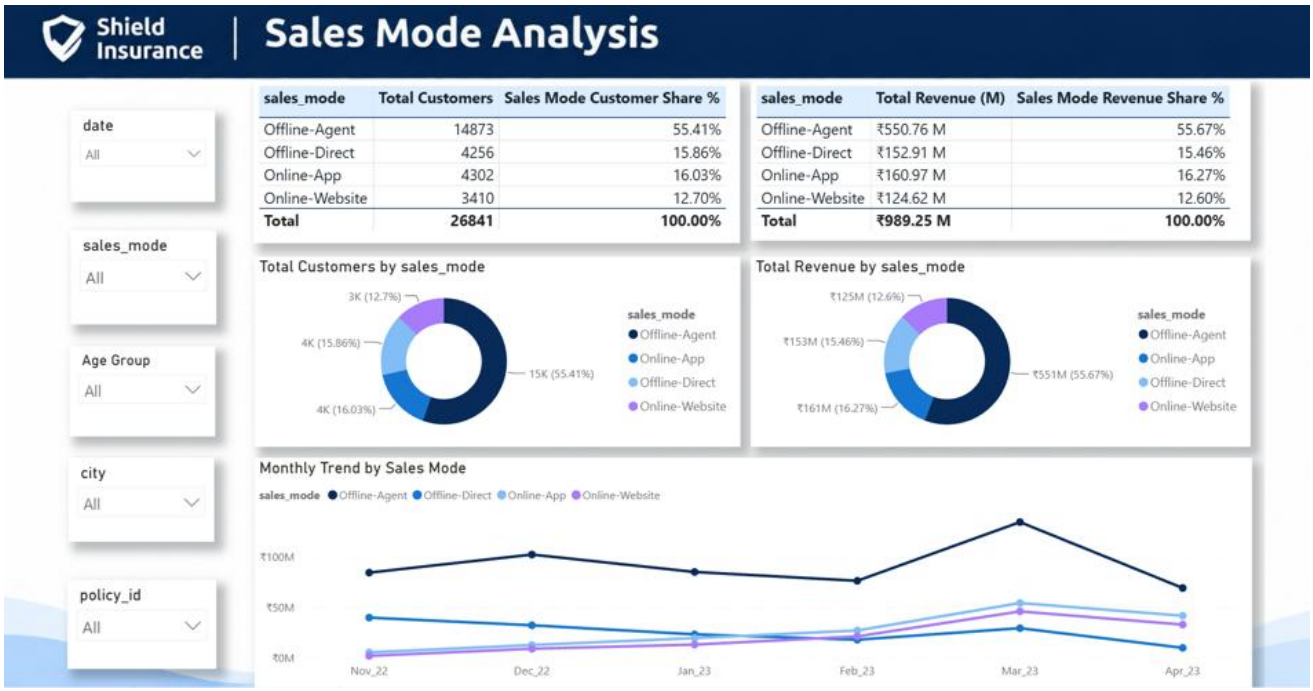

The adjacent age-group table adds revenue and revenue share, allowing the reader to distinguish customer volume from premium contribution. A segment may have fewer customers but higher average revenue per customer.

4.7 Suggested questions for a business review

- Is revenue moving in the same direction as customer count?

- Which months show the strongest or weakest performance?
- Which cities account for the largest share of customers and premium revenue?
- Does the largest customer age group also generate the largest revenue?
- Is the April decline in row-count policy sales a seasonal pattern, a data-period effect, or something that needs operational investigation?

5. Page 2 – Sales Mode Analysis

Sales Mode Analysis page

5.1 Purpose of this page

This page compares the four sales modes in the dataset. It answers two related but different questions: which channels reach the most customers, and which channels contribute the most premium revenue? It also shows how channel revenue changes month by month.

5.2 Sales mode definitions used in the report

Sales mode	Plain-language description
Offline-Agent	Business recorded under the Offline-Agent sales-mode category.
Offline-Direct	Business recorded under the Offline-Direct sales-mode category.
Online-App	Business recorded under the Online-App sales-mode category.
Online-Website	Business recorded under the Online-Website sales-mode category.

These labels are taken from the source data. The report does not provide further operational definitions of what qualifies a sale for each category; those definitions should be confirmed with the business owner if channel attribution rules are important.

5.3 Customer contribution by sales mode

Sales mode	Customers	Customer share
Offline-Agent	14,873	55.41%
Offline-Direct	4,256	15.86%
Online-App	4,302	16.03%

Online-Website	3,410	12.70%
Total	26,841	100.00%

Offline-Agent is the largest channel by customer reach, accounting for 55.41% of all customers. Online-App and Offline-Direct are close in customer contribution, at 16.03% and 15.86% respectively. Online-Website contributes 12.70%.

5.4 Revenue contribution by sales mode

Sales mode	Revenue	Revenue share
Offline-Agent	₹550.76M	55.67%
Offline-Direct	₹152.91M	15.46%
Online-App	₹160.97M	16.27%
Online-Website	₹124.62M	12.60%
Total	₹989.25M	100.00%

Offline-Agent also leads in premium revenue, contributing 55.67% of the total. Online-App contributes 16.27%, slightly higher than Offline-Direct at 15.46%, even though their customer shares are similar. This is a useful example of why customer share and revenue share should be reviewed separately.

5.5 Donut charts – how to read them

- The customer donut shows the percentage of the customer base attributed to each sales mode.
- The revenue donut shows the percentage of total premium revenue attributed to each sales mode.
- A larger slice means a larger contribution to that particular measure; it does not necessarily mean better profitability.

5.6 Monthly Trend by Sales Mode

The line chart plots monthly premium revenue for each sales mode. Each line represents one channel. The chart helps a reader compare channel trajectories, spot months where a channel rises or falls, and see whether the overall monthly movement is being driven mainly by one channel or by several.

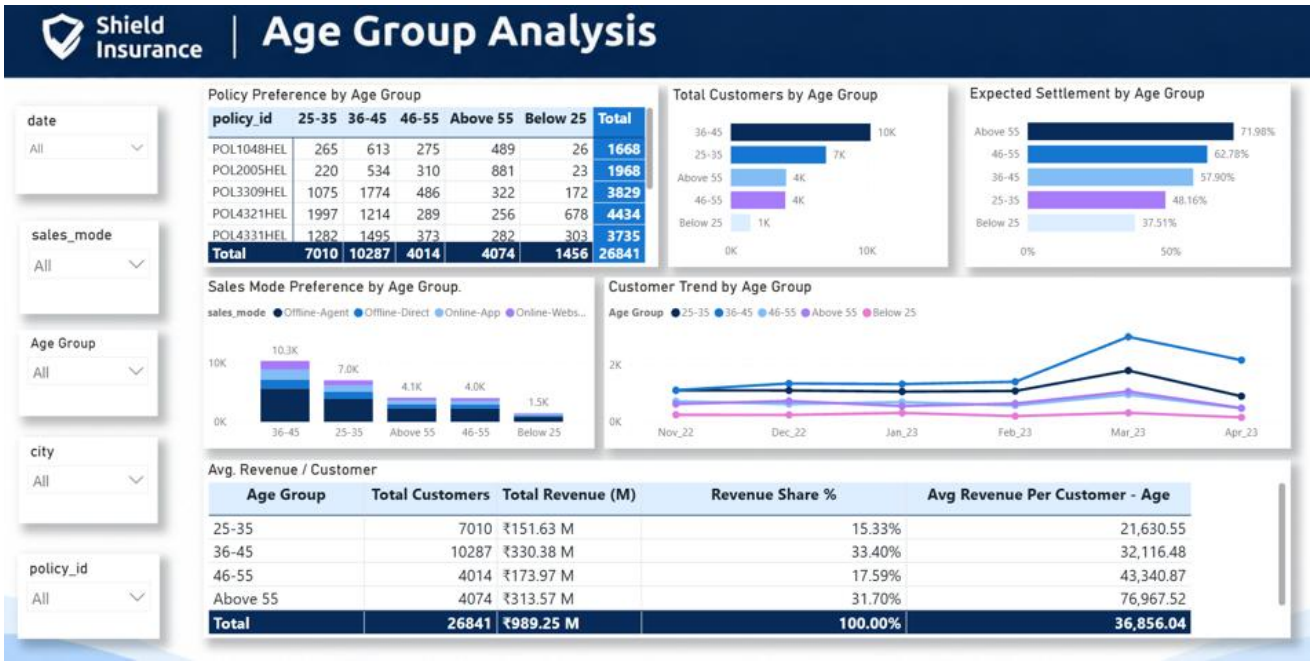

In the displayed chart, Offline-Agent is the largest revenue line throughout the period. The lines for the other three channels are lower and closer together. March 2023 is a high point for several channels, followed by a decline in April.

Do not over-interpret The chart shows recorded monthly revenue by channel. It does not explain the cause of a rise or fall, and it does not measure channel profitability, acquisition cost, conversion rate or customer satisfaction.

5.7 Business questions this page can support

- Which channel contributes the largest customer base?
- Does a channel's revenue share differ from its customer share?
- Are digital channels growing or declining over the six-month period?
- Which channel appears to drive the March peak?
- Should channel strategy discussions focus on reach, revenue, or additional measures such as cost and conversion?

6. Page 3 – Age Group Analysis

Age Group Analysis page

6.1 Purpose of this page

This page explores how customers and recorded premium revenue are distributed across age bands. It also compares policy IDs by age group, sales-mode preference by age group, monthly customer trends, and the settlement percentages available in a separate settlement dataset.

6.2 Policy Preference by Age Group

The matrix places policy IDs in rows and age groups in columns. Each cell shows the value of the measure configured in the visual for that policy-age combination. It helps identify which policy IDs appear more frequently in different age segments. The grand total row and column provide the corresponding totals.

Use this matrix to compare patterns, not to infer product suitability or customer preference without additional context. A larger cell can reflect a larger age group overall; comparisons may need to be normalized by the number of customers in each age band.

6.3 Total Customers by Age Group

Age band	Customers	Approx. share of customers
Below 25	1,456	5.42%
25–35	7,010	26.12%
36–45	10,287	38.31%
46–55	4,014	14.95%
Above 55	4,074	15.18%
Total	26,841	100.00%

The 36–45 segment is the largest by customer count, representing approximately 38.31% of the total customer base. The 25–35 segment is next at approximately 26.12%.

6.4 Expected Settlement by Age Group

Age band	Displayed settlement percentage
Below 25	37.51%
25–35	48.16%
36–45	57.90%
46–55	62.78%
Above 55	71.98%

The visual shows a higher average settlement percentage in the older age bands, with Above 55 at 71.98% and Below 25 at 37.51%. The measure currently shown is an average of settlement percentage values in fact_settlements grouped by age band.

Critical interpretation caveat The settlement table is a separate, disconnected dataset in the current model. The displayed percentages are arithmetic averages of the available settlement percentage values, not necessarily customer-weighted settlement rates, claim approval probabilities, or expected settlement amounts. Do not present them as a forecast of what an individual customer will receive.

6.5 Sales Mode Preference by Age Group

The stacked column chart breaks each age group's customer total into the four sales-mode categories. It is useful for comparing the composition of channel usage across age groups. The total height of a column represents the size of that age segment; the coloured portions show the split by sales mode.

When comparing channel preference, remember that larger age groups naturally tend to have taller columns. To compare preference more directly, compare the relative size of each coloured portion within a group, or use a 100% stacked chart if the business needs normalized proportions.

6.6 Customer Trend by Age Group

This line chart tracks customer counts by age group from November 2022 to April 2023. Each line represents one age band. It helps identify whether customer activity changes similarly across age groups or whether a particular segment has a distinct monthly pattern.

The visible pattern includes a marked March increase for the 36–45 line and a decline in April. The chart is descriptive and should be read with the reporting period and the selected slicers in mind.

6.7 Average Revenue per Customer – Age Group table

Age band	Customers	Revenue	Revenue share	Avg. revenue/customer
Below 25	1,456	₹19.70M	1.99%	₹13,533.34
25–35	7,010	₹151.63M	15.33%	₹21,630.55
36–45	10,287	₹330.38M	33.40%	₹32,116.48
46–55	4,014	₹173.97M	17.59%	₹43,340.87
Above 55	4,074	₹313.58M	31.70%	₹76,967.52
Total	26,841	₹989.25M	100.00%	₹36,856.04

This table is particularly useful because it separates scale from value. The 36–45 group contributes the largest revenue amount (₹330.38M) because it is also the largest customer segment. However, Above 55 has the highest average revenue per customer (₹76,967.52), despite having fewer customers. This indicates a higher recorded premium value per customer in that age segment within this dataset.

6.8 Business questions this page can support

- Which age group is largest by customer count?

- Which age group contributes the most premium revenue?
- Which age group has the highest average revenue per customer?
- Do sales-mode mixes differ across age groups?
- Are there age bands with unusual monthly movement that merit further investigation?
- What additional definitions or source data are required before settlement percentages can support a risk or claims decision?

7. KPI definitions and calculation logic

The following definitions explain the measures used in the report. DAX is included for transparency; a business reader can use the plain-language definition without needing to understand the code.

7.1 Core measures

Measure	Calculation	Business meaning
Total Customers	DISTINCTCOUNT(fact_premiums[customer_code])	Counts each customer code once in the current filter context.
Total Revenue	SUM(fact_premiums[final_premium_amt(INR)])	Adds the final premium amount for all included fact rows.
Monthly Policies Sold	COUNTROWS(fact_premiums)	Counts rows in the premium fact table; valid as policy count only if one row equals one sale.
Average Revenue per Customer	Total Revenue ÷ Total Customers	Average recorded premium revenue per distinct customer in the current context.
Revenue Share %	Segment Revenue ÷ Total Revenue	Shows the selected segment's contribution to overall revenue, subject to the measure's filter logic.
Customer Share %	Segment Customers ÷ Total Customers	Shows the selected segment's contribution to the customer base, subject to the measure's filter logic.

7.2 Daily customer growth

The daily customer growth KPI compares the number of distinct customers on the latest date in the fact data with the number on the previous available date. It is not a month-over-month or year-over-year growth measure.

```
Total Customers =
DISTINCTCOUNT(fact_premiums[customer_code])

Daily Customer Growth Rate =
DIVIDE(
    [Latest Day Customers] - [Previous Available Day Customers],
    [Previous Available Day Customers]
)
```

For the reported latest two dates: 29 April 2023 = 225 customers; 30 April 2023 = 340 customers. The calculation is (340 − 225) / 225 = 51.11%.

7.3 Daily revenue growth

```
Total Revenue =
SUM(fact_premiums[final_premium_amt(INR)])

Daily Revenue Growth Rate =
DIVIDE(
    [Latest Day Revenue] - [Previous Available Day Revenue],
    [Previous Available Day Revenue]
)
```

For the reported latest two dates: 29 April 2023 = ₹8,038,245; 30 April 2023 = ₹13,214,310. The calculation is (₹13,214,310 − ₹8,038,245) / ₹8,038,245 = 64.39%.

7.4 Month-over-month policy sales growth

```
Monthly Policies Sold =
COUNTROWS(fact_premiums)

Policy Sales Previous Month =
CALCULATE(
    [Monthly Policies Sold],
    DATEADD(dim_date[date], -1, MONTH)
)

Policy Sales Growth % =
DIVIDE(
    [Monthly Policies Sold] - [Policy Sales Previous Month],
    [Policy Sales Previous Month]
)
```

The verified monthly values are March 2023 = 7,081 rows and April 2023 = 4,149 rows. The calculation is (4,149 − 7,081) / 7,081 = −41.41%. This means the April row count is 41.41% lower than March.

Context matters DATEADD shifts the current date context back one month. The measure does not automatically force a comparison of the latest month against the previous month in every possible visual context. Its displayed result depends on the date context supplied by the visual and slicers.

8. Data sources and model overview

The report was built from five CSV source files. The premium fact table is the central transaction table; the dimension tables provide descriptive information used to group and filter those transactions.

Source file	Role in the report	Key fields / content
fact_premiums.csv	Main transaction fact table	date, customer_code, policy_id, sales_mode, final_premium_amt(INR)
dim_customer.csv	Customer attributes	customer_code, DOB, city
dim_date.csv	Calendar attributes	date, mmm_yy, day_type, week_no and other date descriptors
dim_policies.csv	Policy attributes	policy_id, base_cover, base_premium_amt(INR)
fact_settlements.csv	Settlement percentage information	age, settlement %

8.1 Intended relationship structure

From	To	Purpose
dim_date[date]	fact_premiums[date]	Connects calendar dates to premium transactions.
dim_customer[customer_code]	fact_premiums[customer_code]	Connects customer attributes such as DOB and city to premium transactions.
dim_policies[policy_id]	fact_premiums[policy_id]	Connects policy attributes to premium transactions.
fact_settlements	No relationship in current model	No shared customer or policy key is available to establish a valid row-level relationship.

Model verification item The customer relationship was previously observed as 1:1 with both-direction filtering in Power BI. The intended dimensional design is normally one customer row per customer_code related to many premium fact rows. Confirm the actual relationship cardinality and filter direction in the PBIX before describing it as a verified one-to-many relationship.

8.2 Date handling

- The premium data covers 1 November 2022 to 30 April 2023.
- The date dimension should contain one unique row per calendar date and a continuous date range.
- The month label mmm_yy should sort by a numeric YearMonthSort column, such as YEAR(date) × 100 + MONTH(date), so that months appear chronologically.
- The date dimension should be marked as the model's date table in Power BI.

8.3 Age calculation and banding

Customer age is derived from the customer's date of birth and the premium transaction date, rather than simply using age at the time the report is viewed. The previously documented approach uses DATEDIFF between DOB and the transaction date. The current screenshots display five bands: Below 25, 25–35, 36–45, 46–55 and Above 55.

Band definition to confirm An earlier draft of the metric specification listed different age bands (18–24, 25–30, 31–40, 41–50, 51–65 and 66+). The current report screenshots show five broader bands. This guide documents the bands visible in the current dashboard; confirm the agreed business definitions before external publication.

9. Key business observations from the displayed report

Observation	Evidence in the report	Reasonable interpretation
Offline-Agent is the dominant channel	55.41% of customers and 55.67% of revenue	The channel is the largest contributor in this dataset by both reach and premium value.
Delhi NCR is the largest city segment	11,007 customers; ₹401.57M revenue; 41.01% customer share	A large portion of recorded business is concentrated in Delhi NCR.
36–45 is the largest age segment	10,287 customers; ₹330.38M revenue	This group contributes the highest customer count and the highest total revenue.
Above 55 has the highest average revenue/customer	₹76,967.52 per customer	Recorded premium value per customer is highest in this age band.
April policy-row volume is below March	4,149 in April versus 7,081 in March; −41.41%	The month-to-month decline is a signal to investigate, not proof of a cause.
Average settlement % rises across displayed age bands	37.51% Below 25 to 71.98% Above 55	The source settlement percentages show this pattern, but the disconnected dataset and averaging method limit interpretation.

These are descriptive observations, not recommendations to increase or reduce exposure to a customer group or sales channel. Additional measures—such as profitability, claims frequency, acquisition cost, persistency, policy tenure and renewal status—would be needed for those decisions.

10. Data limitations, assumptions and interpretation safeguards

- Reporting period: the premium dataset covers six months, from November 2022 through April 2023. It does not establish a full-year or long-term trend.
- Policy movement: the supplied premium data does not include a policy status or transaction type that distinguishes new business, renewals and cancellations. The dashboard therefore cannot reliably report separate new, renewed or cancelled policy counts.
- Policy count grain: the current monthly policy measure counts fact_premiums rows. Confirm that one row equals one policy sale before describing the result as a unique policy count.
- Settlement data: fact_settlements is disconnected from the premium/customer model because no common customer or policy key is available. Its average percentages should not be treated as customer-linked claim outcomes or expected settlement amounts.
- Age bands: the visible dashboard uses five bands. A previous draft specification used six different bands. Confirm the approved segmentation rules.

- Growth KPIs: daily growth compares the last two available transaction dates, not necessarily consecutive calendar days. It is a short-term movement indicator and can be volatile.
- Filter context: some KPI calculations explicitly remove date-table filters to find the latest available date. Other slicers may still affect results depending on the DAX and model relationships.
- Revenue meaning: Total Revenue is the sum of final premium amounts in the supplied file. It should not automatically be described as earned revenue, recognized accounting revenue, gross written premium or net revenue unless that definition is confirmed.
- Profitability: no claims cost, commission, operating expense, acquisition cost or margin measure is shown. A high-revenue segment is not necessarily a high-profit segment.
- Market share: city and channel percentages are shares within this dataset, not shares of the external insurance market.

11. Recommended way to present the dashboard to a stakeholder

A simple walkthrough for Mathew can follow this sequence:

6. Begin on the Home page and explain that the report has three analytical views: overall business performance, sales-channel performance and age-group performance.
7. Open Business Overview. Start with the total customer base and total premium revenue, then explain the daily growth cards and monthly trends. Move to city and age splits to show where the recorded business is concentrated.
8. Open Sales Mode Analysis. Explain that the customer table measures reach while the revenue table measures premium contribution. Point out that Offline-Agent is the largest channel on both measures, while Online-App contributes slightly more revenue than Offline-Direct.
9. Open Age Group Analysis. Explain customer volume first, then total revenue and average revenue per customer. Highlight that 36–45 is largest by volume and total revenue, whereas Above 55 has the highest average revenue per customer.
10. Explain the settlement chart carefully as an average of values from a separate dataset, not as an individualized or weighted expected payout.
11. Close with the limitations: the six-month period, row-count policy metric, lack of new/renewal/cancellation status, and settlement-data linkage limitation.

12. Glossary – plain-English definitions

Term	Meaning
KPI	Key Performance Indicator – a headline measure used to monitor performance.
Premium	The amount recorded as premium in the supplied insurance dataset.
Fact table	A table containing business events or transactions, such as premium records.
Dimension table	A descriptive table used to categorize or filter facts, such as customer, date or policy information.
Distinct count	Counts unique values once, even if they appear in multiple rows.
Revenue contribution / share	A segment's revenue divided by the total revenue in the selected context.
Customer contribution / share	A segment's distinct customer count divided by the total customer count in the selected context.
MoM	Month over Month – comparison of one month with the preceding month.
Growth rate	The change from an earlier value to a later value, divided by the earlier value.
Slicer	An interactive filter control on a Power BI report page.
Filter context	The set of filters currently affecting a measure or visual.
Disconnected table	A table that has no model relationship to the other tables; its values do not automatically filter with them.

Average revenue per customer	Total revenue divided by distinct customers for the same segment and filter context.

13. Suggested next enhancements (outside the current report scope)

These are potential future improvements, not features currently claimed by this dashboard.

- Confirm the transaction grain and, if appropriate, add a unique policy count using DISTINCTCOUNT(policy_id).
- Obtain policy status and transaction type to distinguish new business, renewals, cancellations and endorsements.
- Add claims count, claim amount, settlement amount and a clearly defined settlement-rate denominator, with a valid key to connect outcomes to policies or customers.
- Add profitability measures such as commission, acquisition cost, claims cost and contribution margin if the source data supports them.
- Add a longer reporting history to distinguish seasonal patterns from short-term fluctuations.
- Document the official definitions of each sales mode and the approved age-band boundaries.

14. Final handover summary

The Shield Insurance Power BI report provides a structured view of customer count, premium revenue, daily and monthly movement, city contribution, sales-mode contribution and age-group patterns for the period November 2022 to April 2023. Its three analytical pages are intended to be read together: Business Overview establishes the overall picture, Sales Mode Analysis explains channel contribution, and Age Group Analysis explores customer-segment differences.

The most important displayed findings are that Offline-Agent is the largest sales mode, Delhi NCR is the largest city segment, 36–45 is the largest age group by customers and total revenue, and Above 55 has the highest average revenue per customer. The April policy-row count is 41.41% lower than March. These findings are useful starting points for business discussion, provided the metric definitions and limitations in this guide are retained.

Handover note Before using the report for formal external reporting, confirm the policy-row grain, customer relationship cardinality, approved age-band definitions, and the intended interpretation of the settlement percentage visual.
